#### Abstract

Based on the low－energy effective Hamiltonian with generalized QCD factorization，we calculate the new physics contributions to $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ polarization anomaly and $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}} C P$ asymmetry induced by the neutral Higgs bosons $\mathrm{H}^{0}, \mathrm{~h}^{0}$ and $\mathrm{A}^{0}$ of the two Higgs doublet model III．Within reasonable ranges of parameters，simultaneous solutions to the anomalies of the two processes give out $147<\left|\lambda_{\text {bs }} \lambda_{\text {ss }}\right|<165$ ．It will be really interesting in searching for the signs of new physics．

Key words two Higgs doublet model III，QCD factorization，flavor changing neutral currents

## 1 Introduction

Looking for the signals of new physics（NP）be－ yond the Standard Model（SM）is one of the most im－ portant missions of high energy physics．The study of B physics is of great importance for testing indirect signals of new physics．In this respect，SLAC and KEK are doing a commendable job by providing us with a huge amount of data on various B－meson de－ cays．Most of the experimental measurements are in perfect agreement with the SM．However，there still exist some puzzles observed in exclusive B－meson de－ cays．Such as the abnormally small longitudinal po－ larizations fractions in $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay ${ }^{[1-6]}$ and the anomaly in the time－dependent $C P$ asymmetry $S_{\phi \mathrm{K}_{\mathrm{S}}}$ for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay ${ }^{[7-10]}$ ．Confronted with these anomalies，we are forced not only to consider more precise QCD effects，but also to speculate on the ex－ istence of possible new physics．

The recent experimental results for the longitudi－ nal polarizations fractions in $B_{d}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay are
given as

$$
\begin{align*}
& f_{\mathrm{L}}=0.52 \pm 0.05 \pm 0.02 \\
& \text { BARBAR }^{[1]},  \tag{1}\\
& f_{\mathrm{L}}=0.45 \pm 0.05 \pm 0.02 \\
& \text { Belle }^{[2]}, \\
& f_{\mathrm{L}}=0.57 \pm 0.10 \pm 0.05
\end{align*} \text { CDF }^{[3]} .
$$

The $C P$ asymmetry for the $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay is given as

$$
\begin{align*}
S_{\phi K_{\mathrm{S}}} & =0.19 \pm 0.32 \\
A_{\phi \mathrm{K}_{\mathrm{S}}} & =0.12 \pm 0.20 \text { Belle }^{[7]}  \tag{2}\\
S_{\phi K_{\mathrm{S}}} & =0.50 \pm 0.25_{-0.04}^{+0.07} \\
A_{\phi K_{\mathrm{S}}} & =0.00 \pm 0.23 \pm 0.05 \mathrm{BaBar}^{[8]} . \tag{3}
\end{align*}
$$

It is well known that the flavor changing neutral current（FCNC）processes arise only from loop ef－ fects within the $S M$ ．Since $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ and $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decays are the $\overline{\mathrm{b}} \rightarrow \overline{\mathrm{s} s} \bar{s}$ pure penguin process，they could be used as effective probes of NP scenarios． Especially，using PQCD approach，the abnormally small longitudinal polarizations in $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ de－ cay in the two Higgs doublet model（2HDM）III have been studied ${ }^{[4]}$ ．Moreover，the solution to the

[^0]anomaly in the time－dependent $C P$ asymmetry $S_{\phi \mathrm{K}_{\mathrm{S}}}$ for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay is also discussed by Ref．［10］．In this paper，we use QCD factorization approach ${ }^{[6]}$ and try to provide simultaneous solutions to the abnor－ mally small longitudinal polarizations in $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay and the anomaly in the time－dependent $C P$ asymmetry $S_{\phi K_{\mathrm{S}}}$ for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay within the rea－ sonable parameter space of the 2 HDM III．

## 2 The general characteristics of 2HDM III

One of the most popular extensions of the SM is the so－called two Higgs doublet model，which has two complex Higgs doublets instead of only one in the SM． The cases of the same or the two different Higgs fields to up－and down－type quarks are called model I or model II．While in 2HDM III，both the doublets can couple to the up－and down－type quarks ${ }^{[11,12]}$ ．

Generally we can write down Yukawa Lagrangian for model III ${ }^{[11-13]}$

$$
\begin{align*}
\mathscr{L}_{\mathrm{Y}}= & \eta_{i j}^{U} \bar{Q}_{i, \mathrm{~L}} \tilde{\phi}_{1} U_{j, \mathrm{R}}+\eta_{i j}^{D} \bar{Q}_{i, \mathrm{~L}} \phi_{1} D_{j, \mathrm{R}}+ \\
& \xi_{i j}^{U} \bar{Q}_{i, \mathrm{~L}} \tilde{\phi}_{2} U_{j, \mathrm{R}}+\xi_{i j}^{D} \bar{Q}_{i, \mathrm{~L}} \phi_{2} D_{j, \mathrm{R}}+\text { h.c. } \tag{4}
\end{align*}
$$

where $\phi_{i}(i=1,2$,$) denote the two scalar doublets，$ $\tilde{\phi}_{1,2}=\mathrm{i} \tau_{2} \phi_{1,2}^{*}, Q_{i, \mathrm{~L}}$ with $i=(1,2,3)$ is the left－handed fermion doublet，$U_{j, \mathrm{R}}$ and $D_{j, \mathrm{R}}$ are the right－handed singlets．$Q_{i, \mathrm{~L}}, U_{j, \mathrm{R}}$ and $D_{j, \mathrm{R}}$ are all weak eigenstates， which can be rotated into mass eigenstates．While $\eta^{U, D}$ and $\xi^{U, D}$ are generally the non－diagonal matri－ ces of the Yukawa coupling．

One can express $\phi_{1}$ and $\phi_{2}$ in a suitable basis such that only the first doublet generates all the gauge－ boson and fermion masses，i．e．，such that

$$
\left\langle\phi_{1}\right\rangle=\left(\begin{array}{c}
0  \tag{5}\\
v \\
\frac{\sqrt{2}}{2}
\end{array}\right), \quad\left\langle\phi_{2}\right\rangle=0
$$

The two doublets in the basis then have the form

$$
\begin{align*}
\phi_{1} & =\frac{1}{\sqrt{2}}\left[\binom{0}{v+\chi_{1}^{0}}+\binom{\sqrt{2} G^{+}}{\mathrm{i} G^{0}}\right] \\
\phi_{2} & =\frac{1}{\sqrt{2}}\binom{\sqrt{2} H^{+}}{\chi_{2}^{0}+\mathrm{i} A^{0}} \tag{6}
\end{align*}
$$

where $\mathrm{G}^{0, \pm}$ are the Goldstone bosons that would be
eaten away in the Higgs mechanism to become the longitudinal components of the weak gauge bosons． $\mathrm{H}^{ \pm}$and $\mathrm{A}^{0}$ are the physical charged Higgs boson and $C P$－odd neutral Higgs boson，respectively．$\chi_{1}^{0}$ and $\chi_{2}^{0}$ are not the neutral mass eigenstates but linear com－ binations of the $C P$－even neutral Higgs boson mass eigenstates $\mathrm{H}^{0}$ and $\mathrm{h}^{0}$

$$
\begin{align*}
& \chi_{1}^{0}=H^{0} \cos \alpha-h^{0} \sin \alpha  \tag{7}\\
& \chi_{2}^{0}=H^{0} \sin \alpha+h^{0} \cos \alpha \tag{8}
\end{align*}
$$

where $\alpha$ is the mixing angle，the advantage of choos－ ing the basis is no couplings of the form $\chi_{2}^{0} \mathrm{ZZ}$ and $\chi_{2}^{0} \mathrm{~W}^{+} \mathrm{W}^{-}$．

After the diagonalization of mass matrix of the fermions fields，the Yukawa Lagrangian becomes

$$
\begin{align*}
\mathscr{L}_{\mathrm{YC}}= & \hat{\eta}_{i j}^{U} \bar{Q}_{i, \mathrm{~L}} \tilde{\phi}_{1} U_{j, \mathrm{R}}+\hat{\eta}_{i j}^{D} \bar{Q}_{i, \mathrm{~L}} \phi_{1} D_{j, \mathrm{R}}+ \\
& \hat{\xi}_{i j}^{U} \bar{Q}_{i, \mathrm{~L}} \tilde{\phi}_{2} U_{j, \mathrm{R}}+\hat{\xi}_{i j}^{D} \bar{Q}_{i, \mathrm{~L}} \phi_{2} D_{j, \mathrm{R}}+\text { h.c. } \tag{9}
\end{align*}
$$

where $Q_{i, \mathrm{~L}}, U_{j, \mathrm{R}}$ ，and $D_{j, \mathrm{R}}$ denote the fermion fields which are in mass eigenstates and

$$
\begin{align*}
& \hat{\eta}^{U, D}=\left(V_{\mathrm{L}}^{U, D}\right)^{-1} \cdot \eta^{U, D} \cdot V_{\mathrm{R}}^{U, D}=\frac{\sqrt{2}}{v} M^{U, D}  \tag{10}\\
& \hat{\xi}^{U, D}=\left(V_{\mathrm{L}}^{U, D}\right)^{-1} \cdot \xi^{U, D} \cdot V_{\mathrm{R}}^{U, D} \tag{11}
\end{align*}
$$

$V_{\mathrm{L}, \mathrm{R}}^{U, D}$ are the rotation matrices acting on the up－ and down－type quarks，with left or right chirality，re－ spectively．$\quad V_{\mathrm{CKM}}=\left(V_{\mathrm{L}}^{U}\right)^{\dagger} V_{\mathrm{L}}^{D}$ is the usual Cabibbo－ Kobayashi－Maskawa（CKM）matrix．From Eq．（9）， one can see that the matrices $\hat{\xi}^{U, D}$ allow scalar－ mediated FCNC，and in the quark mass basis only the matrices $\hat{\eta}^{U, D}$ are diagonal，but the matrices $\hat{\xi}^{U, D}$ are in general not diagonal．

The matrix $\hat{\xi}^{U, D}$ contain the FCNC couplings．In this paper，we use the Cheng－Sher relation ${ }^{[13]}$

$$
\begin{equation*}
\xi_{i j}^{U, D}=\lambda_{i j} \frac{\sqrt{m_{i} m_{j}}}{v} \tag{12}
\end{equation*}
$$

by which the quark－mass hierarchy ensures that the FCNC within the first two generations are naturally suppressed by the small quark masses，while a large freedom is allowed for the FCNC involving the third generations．

## 3 Polarization anomaly of $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \boldsymbol{\phi} \mathrm{~K}^{* 0}$ decay

In SM，the analysis of the $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay can be performed in terms of an effective low energy theory with the Hamiltonian ${ }^{[14]}$

$$
\begin{equation*}
H_{\mathrm{eff}}^{\mathrm{SM}}=-\frac{G_{\mathrm{F}}}{\sqrt{2}} V_{\mathrm{tb}} V_{\mathrm{ts}}^{*} \sum_{i=3}^{10} C_{i} O_{i} . \tag{13}
\end{equation*}
$$

The amplitude for the decay can be written as ${ }^{[6]}$

$$
\begin{equation*}
A_{\lambda}=-\frac{G_{\mathrm{F}}}{\sqrt{2}} V_{\mathrm{tb}} V_{\mathrm{ts}}^{*} a_{\lambda}\left(\phi \mathrm{K}^{* 0}\right) X^{\left(\mathrm{BK}^{* 0}, \phi\right)} \tag{14}
\end{equation*}
$$

where

$$
\begin{align*}
X^{\left(\mathrm{BK}^{* 0}, \phi\right)}= & \langle\phi| \bar{s} \gamma_{\mu} s|0\rangle\left\langle K^{* 0}\right| \bar{s} \gamma^{\mu}\left(1-\gamma_{5}\right) b|B\rangle= \\
& \mathrm{i} f_{\phi} M_{\phi}\left[\varepsilon_{1}^{*} \cdot \varepsilon_{2}^{*}\left(M_{\mathrm{B}}+M_{\mathrm{K}^{* 0}}\right) A_{1}\left(M_{\phi}^{2}\right)-\right. \\
& \left(\varepsilon_{1}^{*} \cdot P_{\mathrm{B}}\right)\left(\varepsilon_{2}^{*} \cdot P_{\mathrm{B}}\right) \frac{2 A_{2}\left(M_{\phi}^{2}\right)}{M_{\mathrm{B}}+M_{\mathrm{K}^{* 0}}}+ \\
& \left.\mathrm{i} \epsilon_{\mu \nu \alpha \beta} \varepsilon_{2}^{* \mu} \varepsilon_{1}^{* \nu} P_{\mathrm{B}}^{\alpha} P_{\mathrm{K}^{* 0}}^{\sigma} \frac{2 V\left(M_{\phi}^{2}\right)}{M_{\mathrm{B}}+M_{\mathrm{K}^{* 0}}}\right], \tag{15}
\end{align*}
$$

and $a_{\lambda}\left(\phi \mathrm{K}^{* 0}\right)$ is the effective coefficient which de－ pends on the factorization approach．

Since B meson is a pseudoscalar，the final two vector mesons must have the same helicity．In the helicity basis，taking the $\phi\left(\mathrm{K}^{* 0}\right)$ meson flying in the minus（plus）$z$－direction and using the sign conven－ tion $\epsilon^{0123}=-1$ ，the amplitude can be decomposed into three helicity amplitudes

$$
\begin{align*}
H_{0}= & \frac{G_{\mathrm{F}}}{\sqrt{2}} V_{\mathrm{tb}} V_{\mathrm{ts}}^{*} a_{0}\left(\phi \mathrm{~K}^{* 0}\right) \frac{\mathrm{i} f_{\phi}}{2 M_{\mathrm{K}^{* 0}}} \times \\
& {\left[\left(M_{\mathrm{B}}^{2}-M_{\mathrm{K}^{* 0}}^{2}-M_{\phi}^{2}\right)\left(M_{\mathrm{B}}+M_{\mathrm{K}^{* 0}}\right) A_{1}\left(M_{\phi}^{2}\right)-\right.} \\
& \left.\frac{4 M_{\mathrm{B}}^{2} p_{\mathrm{c}}^{2} A_{2}\left(M_{\phi}^{2}\right)}{M_{\mathrm{B}}+M_{\mathrm{K}^{* 0}}}\right],  \tag{16}\\
H_{ \pm}= & \mathrm{i} \frac{G_{\mathrm{F}}}{\sqrt{2}} V_{\mathrm{tb}} V_{\mathrm{ts}}^{*} a_{ \pm}\left(\phi \mathrm{K}^{* 0}\right) M_{\phi} f_{\phi} \times \\
& {\left[\left(M_{\mathrm{B}}+M_{\mathrm{K}^{*} 0}\right) A_{1}\left(M_{\phi}^{2}\right) \mp \frac{2 M_{\mathrm{B}} p_{\mathrm{c}}}{M_{\mathrm{B}}+M_{\mathrm{K}}{ }^{* 0}} V\left(M_{\phi}^{2}\right)\right], }
\end{align*}
$$

where

$$
\begin{equation*}
p_{\mathrm{c}}=\frac{\sqrt{\left[M_{\mathrm{B}}^{2}-\left(M_{\mathrm{K} * 0}+M_{\Phi}\right)^{2}\right]\left[M_{\mathrm{B}}^{2}-\left(M_{\mathrm{K} * 0}-M_{\Phi}\right)^{2}\right]}}{2 M_{\mathrm{B}}} \tag{17}
\end{equation*}
$$

denotes the center of mass momentum of the meson $\phi$ or $\mathrm{K}^{* 0}$ in the $\mathrm{B}_{\mathrm{d}}^{0}$ rest frame．

Then the branching ratio is written as

$$
\begin{equation*}
B_{\mathrm{r}}=\frac{\tau_{\mathrm{B}} p_{\mathrm{c}}}{8 \pi M_{\mathrm{B}}^{2}}\left(\left|H_{0}\right|^{2}+\left|H_{+}\right|^{2}+\left|H_{-}\right|^{2}\right) \tag{18}
\end{equation*}
$$

and the longitudinal and the transverse polarization rates are

$$
\begin{align*}
f_{\mathrm{L}} & =\frac{\Gamma_{\mathrm{L}}}{\Gamma}=\frac{\left|H_{0}\right|^{2}}{\left|H_{0}\right|^{2}+\left|H_{+}\right|^{2}+\left|H_{-}\right|^{2}},  \tag{19}\\
f_{\mathrm{T}} & =\frac{\Gamma_{\mathrm{T}}}{\Gamma}=\frac{\left|H_{+}\right|^{2}+\left|H_{-}\right|^{2}}{\left|H_{0}\right|^{2}+\left|H_{+}\right|^{2}+\left|H_{-}\right|^{2}} .
\end{align*}
$$

FCNC processes could happen at one loop level in the SM，but are suppressed by the GIM mechanism． The discrepancy between the SM result and the B factory data indicates the presence of NP which may enter through new FCNC processes arising at the tree level．

In this paper，we only consider fermions couplings with the neutral gauge bosons $\mathrm{H}^{0}, \mathrm{~h}^{0}$ ，and $\mathrm{A}^{0}$ in the 2HDM III．The FCNC part of the Yukawa Lagrangian could be ${ }^{[11,15]}$

$$
\begin{align*}
\mathscr{L}_{\mathrm{Y}, \mathrm{FCNC}}= & -\frac{H^{0} \sin \alpha+h^{0} \cos \alpha}{\sqrt{2}} \times \\
& \left\{\bar{D}\left[\hat{\xi}^{D} \frac{1}{2}\left(1+\gamma_{5}\right)+\hat{\xi}^{D \dagger} \frac{1}{2}\left(1-\gamma_{5}\right)\right] D\right\}- \\
& \frac{\mathrm{i} A^{0}}{\sqrt{2}}\left\{\bar{D}\left[\hat{\xi}^{D} \frac{1}{2}\left(1+\gamma_{5}\right)-\hat{\xi}^{D \dagger} \frac{1}{2}\left(1-\gamma_{5}\right)\right] D\right\}- \\
& \frac{g}{2 M_{\mathrm{W}}}\left(H^{0} \cos \alpha-h^{0} \sin \alpha\right) \bar{D} M_{\mathrm{D}} D \tag{20}
\end{align*}
$$

where $\alpha$ is the mixing angle，$D$ represents the mass eigenstates of down－type quarks．We only consider s quark in this paper．$\xi^{D}$ is defined by Eq．（11）．

The effective Hamiltonians of the $\overline{\mathrm{b}} \rightarrow \overline{\mathrm{s}} \mathrm{s} \overline{\mathrm{s}}$ tran－ sition mediated by the $\mathrm{H}^{0}, \mathrm{~h}^{0}$ ，and $\mathrm{A}^{0}$ are given by， respectively

$$
\begin{align*}
H_{\mathrm{eff}}^{\mathrm{H}^{0}}= & -\frac{\sqrt{2} G_{\mathrm{F}}}{2 M_{\mathrm{H}^{0}}^{2}} \sin ^{2} \alpha m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}} \times \\
& {\left[\lambda_{\mathrm{ss}} \lambda_{\mathrm{bs}}^{*}\left(O_{7}+O_{9}\right)+\lambda_{\mathrm{ss}}^{*} \lambda_{\mathrm{bs}}\left(O_{7}^{\prime}+O_{9}^{\prime}\right)\right] }  \tag{21}\\
H_{\mathrm{eff}}^{\mathrm{h}^{0}}= & -\frac{\sqrt{2} G_{\mathrm{F}}}{2 M_{\mathrm{h}^{0}}^{2}} \cos ^{2} \alpha m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}} \times \\
& {\left[\lambda_{\mathrm{ss}} \lambda_{\mathrm{bs}}^{*}\left(O_{7}+O_{9}\right)+\lambda_{\mathrm{ss}}^{*} \lambda_{\mathrm{bs}}\left(O_{7}^{\prime}+O_{9}^{\prime}\right)\right], }  \tag{22}\\
H_{\mathrm{eff}}^{\mathrm{A}^{0}}= & -\frac{\sqrt{2} G_{\mathrm{F}}}{2 M_{\mathrm{A}^{0}}^{2}} m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}} \times \\
& {\left[\lambda_{\mathrm{ss}} \lambda_{\mathrm{bs}}^{*}\left(O_{7}+O_{9}\right)+\lambda_{\mathrm{ss}}^{*} \lambda_{\mathrm{bs}}\left(O_{7}^{\prime}+O_{9}^{\prime}\right)\right], } \tag{23}
\end{align*}
$$

where the constant term，and the coefficients of $\lambda_{\mathrm{ss}}\left(\lambda_{\mathrm{ss}}^{*}\right), \lambda_{\mathrm{bs}}\left(\lambda_{\mathrm{bs}}^{*}\right)$ terms which are 100 times smaller than the coefficients of $\lambda_{\mathrm{bs}} \lambda_{\mathrm{bs}}^{*}, \lambda_{\mathrm{bs}}^{*} \lambda_{\mathrm{bs}}$ ，so we have ne－ glected them in the upper Eqs．（20－22）．$H_{\text {eff }}^{\mathrm{H}^{0}}, H_{\mathrm{eff}}^{\mathrm{h}^{0}}$ ， and $H_{\text {eff }}^{\mathrm{A}^{0}}$ have the same operators $O_{7}$ and $O_{9}$ as in the SM effective Hamiltonian，$O_{7}^{\prime}$ and $O_{9}^{\prime}$ are new operators

$$
\begin{equation*}
O_{7}^{\prime}=(\overline{\mathrm{q}} \mathrm{q})_{V-A}(\overline{\mathrm{~b}})_{V+A}, \quad O_{9}^{\prime}=(\overline{\mathrm{q}} \mathrm{q})_{V+A}(\overline{\mathrm{bs}})_{V+A} \tag{24}
\end{equation*}
$$

the hadronic matrix elements of these operators are calculated up to the $\alpha_{\mathrm{s}}$ order using the QCD factor－ ization approach in this paper．For convenience，we assume that $\lambda_{\mathrm{ss}}$ is real，and $\lambda_{\mathrm{bs}}=\left|\lambda_{\mathrm{bs}}\right| \mathrm{e}^{\mathrm{i} \phi}$ ．

The additional contributions to the SM Wilson coefficients at the $M_{\mathrm{W}}$ scale are

$$
\begin{align*}
\Delta C_{7}= & \Delta C_{9}=m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}} \frac{\left|V_{\mathrm{tb}} V_{\mathrm{ts}}^{*}\right|}{V_{\mathrm{tb}} V_{\mathrm{ts}}^{*}} \times \\
& \left(\frac{\sin ^{2} \alpha}{M_{\mathrm{H}^{0}}^{2}}+\frac{\cos ^{2} \alpha}{M_{\mathrm{h}^{0}}^{2}}+\frac{1}{M_{\mathrm{A}^{0}}^{2}}\right)\left|\lambda_{\mathrm{bs}}^{*} \lambda_{\mathrm{ss}}\right| \mathrm{e}^{\mathrm{i} \phi}= \\
& -m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}}\left(\frac{\sin ^{2} \alpha}{M_{\mathrm{H}^{0}}^{2}}+\frac{\cos ^{2} \alpha}{M_{\mathrm{h}^{0}}^{2}}+\frac{1}{M_{\mathrm{A}^{0}}^{2}}\right) \times \\
& \left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right| \mathrm{e}^{-\mathrm{i} \phi} . \tag{25}
\end{align*}
$$

The new operators contribution to the Wilson co－ efficients at the $M_{\mathrm{W}}$ scale are

$$
\begin{align*}
\Delta C_{7}^{\prime}= & \Delta C_{9}^{\prime}=m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}} \frac{\left|V_{\mathrm{tb}} V_{\mathrm{ts}}^{*}\right|}{V_{\mathrm{tb}} V_{\mathrm{ts}}^{*}} \times \\
& \left(\frac{\sin ^{2} \alpha}{M_{\mathrm{H}^{0}}^{2}}+\frac{\cos ^{2} \alpha}{M_{\mathrm{h}^{0}}^{2}}+\frac{1}{M_{\mathrm{A}^{0}}^{2}}\right)\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}^{*}\right| \mathrm{e}^{\mathrm{i} \phi}= \\
& -m_{\mathrm{s}} \sqrt{m_{\mathrm{b}} m_{\mathrm{s}}}\left(\frac{\sin ^{2} \alpha}{M_{\mathrm{H}^{0}}^{2}}+\frac{\cos ^{2} \alpha}{M_{\mathrm{h}^{0}}^{2}}+\frac{1}{M_{\mathrm{A}^{0}}^{2}}\right) \times \\
& \left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right| \mathrm{e}^{\mathrm{i} \phi} . \tag{26}
\end{align*}
$$

We neglect the renormalization group running be－ tween $M_{\mathrm{W}}$ and $M_{\mathrm{H}^{0}}, M_{\mathrm{h}^{0}}, M_{\mathrm{A}^{0}}$ ．The full description of the running of the Wilson coefficient from the $M_{\mathrm{W}}$ scale to $m_{\mathrm{b}}$ can be found in Ref．［14］．We only re－ peat the directly relevant steps．The renormalization group equation for the Wilson coefficients $\boldsymbol{C}$

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} \ln \mu} \boldsymbol{C}=\gamma^{\mathrm{T}}(g) \boldsymbol{C}(\mu) \tag{27}
\end{equation*}
$$

can be solved with the help of the $U$ matrix which describes the QCD evolution

$$
\begin{equation*}
\boldsymbol{C}(\mu)=U\left(\mu, M_{\mathrm{W}}\right) \boldsymbol{C}\left(M_{\mathrm{W}}\right) \tag{28}
\end{equation*}
$$

where $\gamma^{\mathrm{T}}(g)$ is the transpose of the anomalous dimen－
sion matrix $\gamma(g)$ ．With the help of $\mathrm{d} g / \mathrm{d} \ln \mu=\beta(g)$ ， $U$ obeys the same equation as $\boldsymbol{C}(\mu)$ ．As for the $\Delta C_{9}$ and $\Delta C_{9}^{\prime}$ ，one can get their anomalous dimensions to the first order in $\alpha_{\text {s }}$

$$
\gamma\left(\alpha_{\mathrm{s}}\right)=\frac{\alpha_{\mathrm{s}}}{4 \pi} \gamma^{(0)}=\frac{\alpha_{\mathrm{s}}}{4 \pi}\left(\begin{array}{cc}
-6 / N & 6  \tag{29}\\
6 & -6 / N
\end{array}\right)
$$

and for the $\Delta C_{7}$ and $\Delta C_{7}^{\prime}$ ，we have the opposite anomalous dimension matrix．

We get the total decay amplitude

$$
\begin{equation*}
H_{\lambda}=H_{\lambda}^{\mathrm{SM}}+H_{\lambda}^{\mathrm{new}} \tag{30}
\end{equation*}
$$

where $H_{\lambda}^{\text {new }}$ denotes the contributions from $\mathrm{H}^{0}, \mathrm{~h}^{0}$ ， and $\mathrm{A}^{0}$ ．

Taking into account the constrains on parame－ ters from experimental data and theoretical limits， we take the NLO Wilson coefficients evaluated at the scale of $\mu=m_{\mathrm{b}}{ }^{[14]}$ ，the decay constants $f_{\mathrm{B}}=$ $0.216 \mathrm{GeV}, f_{\phi}=0.231 \mathrm{GeV}$ and the form factors of light－cone QCD sum rules ${ }^{[16,17]}$ ．The integral of B meson light－cone distribution amplitude can be pa－ rameterized as ${ }^{[18]}$

$$
\begin{equation*}
\int_{0}^{1} \mathrm{~d} \xi \frac{\phi_{\mathrm{B}}(\xi)}{\xi}=\frac{M_{\mathrm{B}}}{\Lambda_{\mathrm{B}}} \tag{31}
\end{equation*}
$$

and we take $\Lambda_{\mathrm{B}}=0.35 \mathrm{GeV}$ in our calculations． The logarithmic and linear divergences may be phe－ nomenologically parameterized as ${ }^{[18,19]}$

$$
\begin{equation*}
\int_{0}^{1} \frac{\mathrm{~d} y}{y}=\ln \frac{M_{\mathrm{B}}}{\Lambda_{\mathrm{h}}}, \quad \int_{0}^{1} \frac{\mathrm{~d} y}{y^{2}}=\frac{M_{\mathrm{B}}}{\Lambda_{\mathrm{h}}} \tag{32}
\end{equation*}
$$

with $\Lambda_{\mathrm{h}}=0.5 \mathrm{GeV}$ ．
The parameters in the 2 HDM III can be taken as $\alpha=\frac{\pi}{4}, M_{\mathrm{H}^{0}}=150 \mathrm{GeV}, M_{\mathrm{h}^{0}}=115 \mathrm{GeV}, M_{\mathrm{A}^{0}}=$ $120 \mathrm{GeV}^{[20]}$ ．Considering the NP contributions and combining the theoretical formulas and input param－ eters，the amplitude of $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay depends only on two parameters $\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|$ and $\phi$ ．We can put constraint on the possible regions for the two NP pa－ rameters from the measured branching ratio and the longitudinal polarization of the $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay． Considering the branching ratio at $2 \sigma$ and the longi－ tudinal polarization at $1 \sigma$ ，we give the contour plots for branching ratio and the longitudinal polarization having $\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|$ as a function of the new phase $\phi$ in Fig． 1.

Fig．1．The solid curves are the contour plots for $B r=(9.5 \pm 0.9) \times 10^{-6}$ within $2 \sigma$ and the dashed curves for $f_{\mathrm{L}}=0.49 \pm 0.04$ within $1 \sigma$ ． The central curves are for the central values of $B r$ and $f_{\mathrm{L}}$ ，respectively．

From Fig．1，the experimental values of the branching ratio and the longitudinal polarization for $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay can be obtained simultaneously in the overlapped regions，which are

$$
\begin{equation*}
147<\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|<176 \tag{33}
\end{equation*}
$$

In Ref．［11］， $\mathrm{B}_{\mathrm{s}}^{0}-\overline{\mathrm{B}}_{\mathrm{s}}^{0}$ mixing points out that the $\lambda_{\mathrm{bs}}$ coupling may not be small，it can be somewhat bigger than one，which is a lower bound．The $\lambda_{\text {ss }}$ coupling can be as large as $O(100)$ ，we find that this param－ eter space is reasonable．If the recent experimental measurements on the polarization anomaly are credi－ ble，comparing the former constrains to the coupling parameters，we also obtain more stringent bound．

## $4 \quad C P$ asymmetry for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay

In order to calculate the contributions on $C P$ asymmetry for the $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay，we take

$$
\begin{equation*}
S_{\phi \mathrm{K}_{\mathrm{S}}}=0.40 \pm 0.20, \quad A_{\phi \mathrm{K}_{\mathrm{S}}}=0.07 \pm 0.15 \tag{34}
\end{equation*}
$$

which are the average value of Belle and BARBAR measurements in Eq．（2）and Eq．（3）．

We adopt the QCD factorization for $\mathrm{B} \rightarrow \mathrm{PV}^{[18]}$ ， the decay amplitude $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ is

$$
\begin{align*}
A\left(\mathrm{~B}_{\mathrm{d}} \rightarrow \phi \mathrm{~K}_{\mathrm{S}}\right)= & \frac{G_{\mathrm{F}}}{\sqrt{2}} \sum_{p=\mathrm{u}, \mathrm{c}} \lambda_{\mathrm{p}} a\left(\phi \mathrm{~K}_{\mathrm{S}}\right)\langle\phi| \bar{s} \gamma_{\mu} s|0\rangle \times \\
& \left\langle K_{\mathrm{S}}\right| \bar{s} \gamma^{\mu}\left(1 \mp \gamma_{5}\right) b|B\rangle= \\
& -\mathrm{i} \sqrt{2} G_{\mathrm{F}} \sum_{p=\mathrm{u}, \mathrm{c}} \lambda_{\mathrm{p}} a\left(\phi \mathrm{~K}_{\mathrm{S}}\right) \times \\
& f_{\phi} M_{\phi} F_{1}^{\mathrm{BK}}\left(M_{\phi}^{2}\right)\left(\varepsilon^{*} \cdot P_{\mathrm{B}}\right) \tag{35}
\end{align*}
$$

where $a\left(\phi \mathrm{~K}_{\mathrm{S}}\right)$ is the effective coefficient．
The branching ratio of $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay in the B meson rest frame can be written as

$$
\begin{equation*}
B_{\mathrm{r}}=\frac{\tau_{\mathrm{B}} p_{\mathrm{c}}}{8 \pi M_{\mathrm{B}}^{2}}\left|A\left(\mathrm{~B}_{\mathrm{d}} \longrightarrow \phi \mathrm{~K}_{\mathrm{S}}\right)\right|^{2} \tag{36}
\end{equation*}
$$

where

$$
\begin{equation*}
p_{\mathrm{c}}=\frac{\sqrt{\left[M_{\mathrm{B}}^{2}-\left(M_{\mathrm{K}_{\mathrm{S}}}+M_{\phi}\right)^{2}\right]\left[M_{\mathrm{B}}^{2}-\left(M_{\mathrm{K}_{\mathrm{S}}}-M_{\phi}\right)^{2}\right]}}{2 M_{\mathrm{B}}} \tag{37}
\end{equation*}
$$

denotes the center of mass momentum of the meson $\phi$ or $\mathrm{K}_{\mathrm{S}}$ in the $\mathrm{B}_{\mathrm{d}}$ rest frame．

For the $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay，the time－dependent $C P$ asymmetry is

$$
\begin{align*}
a_{\phi \mathrm{K}_{\mathrm{S}}}= & \frac{\Gamma\left(\overline{\mathrm{B}}^{0}(\mathrm{t}) \rightarrow \phi \mathrm{K}_{\mathrm{S}}\right)-\Gamma\left(\mathrm{B}^{0}(\mathrm{t}) \rightarrow \phi \mathrm{K}_{\mathrm{S}}\right)}{\Gamma\left(\overline{\mathrm{B}}^{0}(\mathrm{t}) \rightarrow \phi \mathrm{K}_{\mathrm{S}}\right)+\Gamma\left(\mathrm{B}^{0}(\mathrm{t}) \rightarrow \phi \mathrm{K}_{\mathrm{S}}\right)}= \\
& A_{\phi \mathrm{K}_{\mathrm{S}}} \cos \left(\Delta M_{\mathrm{B}_{\mathrm{d}}} t\right)+S_{\phi \mathrm{K}_{\mathrm{S}}} \sin \left(\Delta M_{\mathrm{B}_{\mathrm{d}}} t\right) \tag{38}
\end{align*}
$$

where the direct and the indirect $C P$ asymmetry pa－ rameters are given by，respectively

$$
\begin{equation*}
A_{\phi \mathrm{K}_{\mathrm{S}}}=\frac{\left|\lambda_{\phi \mathrm{K}_{\mathrm{S}}}\right|^{2}-1}{\left|\lambda_{\phi \mathrm{K}_{\mathrm{S}}}\right|^{2}+1}, \quad S_{\phi \mathrm{K}_{\mathrm{S}}}=\frac{2 \operatorname{Im}\left[\lambda_{\phi \mathrm{K}_{\mathrm{S}}}\right]}{\left|\lambda_{\phi \mathrm{K}_{\mathrm{S}}}\right|^{2}+1} \tag{39}
\end{equation*}
$$

The parameter $\lambda_{\phi K_{S}}$ is defined by

$$
\begin{equation*}
\lambda_{\phi \mathrm{K}_{\mathrm{S}}} \equiv \eta_{\phi \mathrm{K}_{\mathrm{S}}} \frac{V_{\mathrm{tb}}^{*} V_{\mathrm{td}}}{V_{\mathrm{tb}} V_{\mathrm{td}}^{*}} \cdot \frac{V_{\mathrm{cs}} V_{\mathrm{cd}}^{*}}{V_{\mathrm{cs}}^{*} V_{\mathrm{cd}}} \cdot \frac{\bar{A}\left(\phi \overline{\mathrm{~K}}_{\mathrm{S}}\right)}{A\left(\phi \mathrm{~K}_{\mathrm{S}}\right)} \tag{40}
\end{equation*}
$$

where $\eta_{\phi \mathrm{K}_{\mathrm{S}}}=-1$ is $C P$ eigenvalue of the $\phi \mathrm{K}_{\mathrm{S}}$ state．
Considering the left－handed and right－handed fla－ vor changing couplings from the contributions of $\mathrm{H}^{0}$ ， $\mathrm{h}^{0}$ ，and $\mathrm{A}^{0}$ ，the additional contributions $\Delta C_{9(7)}$ and $\Delta C_{9(7)}^{\prime}$ are the same as in the $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay．

In the QCD factorization approach，we use the same input parameters as the process of $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay，and get the $\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|-\phi$ relations from the con－ tour plots for the branching ratio and the $C P$ asym－ metry in Fig． 2.

Combining the constrains from the branching ra－ tio for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay at $2 \sigma$ and both $A_{\phi \mathrm{K}_{\mathrm{S}}}$ and $S_{\phi \mathrm{K}_{\mathrm{S}}}$ at $2 \sigma$ ，we find that the allowed regions are

$$
\begin{gather*}
140<\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|<165 \\
120<\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|<145  \tag{41}\\
60<\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|<85
\end{gather*}
$$

Fig．2．The solid curves are the contour plots for the current world average value $B r=$ $\left(8.3_{-1.0}^{+1.2}\right) \times 10^{-6}$ within $2 \sigma^{[21]}$ ，the dashed curves and dotted curves are for the current experimental results $S_{\phi \mathrm{K}_{\mathrm{S}}}=0.40 \pm 0.20$ and $A_{\phi \mathrm{K}_{\mathrm{S}}}=0.07 \pm 0.15$ within $2 \sigma$ ，respectively． The central curves are for the central values of branch ratio，$S_{\phi \mathrm{K}_{\mathrm{S}}}$ and $A_{\phi \mathrm{K}_{\mathrm{S}}}$ ，respectively．

## 5 Summary

In summary，in this paper we study the polar－ ization anomaly of the $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay and the anomaly $C P$ asymmetry $S_{\phi \mathrm{K}_{\mathrm{S}}}$ for $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay in the 2 HDM III．We consider the additional con－ tributions from the neutral gauges boson $\mathrm{H}^{0}, \mathrm{~h}^{0}$ ，and $\mathrm{A}^{0}$ ，which induce the FCNCs at the tree level．The ef－ fective Hamiltonian $H_{\mathrm{eff}}^{\mathrm{H}^{0}}$ ，$H_{\mathrm{eff}}^{\mathrm{h}^{0}}$ ，and $H_{\mathrm{eff}}^{\mathrm{A}^{0}}$ include some new operators which do not exist in SM．As some op－ erators in SM，the hadronic matrix elements of the new operators have been calculated up to the $\alpha_{\text {s }}$ or－ der using the QCD factorization approach．We select
$\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|$ and the phase $\phi$ as the parameters and ex－ press the relation of the branching ratio and the lon－ gitudinal polarization，we give out the contour plots for branching ratio and the longitudinal polarization having $\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|$ as a function of the new phase $\phi$ ，and find that the large longitudinal polarization can be reduced to the experimental results within the rea－ sonable parameters．

In the same way，we discuss the $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ decay and show the images of $\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|-\phi$ from the contour plots for the branching ratio and the $C P$ asymmetry．

From Eqs．（33）and（41），we can get the self－ consistent results of

$$
\begin{equation*}
147<\left|\lambda_{\mathrm{bs}} \lambda_{\mathrm{ss}}\right|<165 \tag{42}
\end{equation*}
$$

for the two processes in $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ and $\mathrm{B}_{\mathrm{d}} \rightarrow \phi \mathrm{K}_{\mathrm{S}}$ ． And the results we get naturally are very consistent with the constrains and the assumptions on the model parameters．

In conclusion，we have showed that the polariza－ tion anomaly in $\mathrm{B}_{\mathrm{d}}^{0} \rightarrow \phi \mathrm{~K}^{* 0}$ decay and the anomaly in the time－dependent $C P$ asymmetry $S_{\phi \mathrm{K}_{\mathrm{S}}}$ for $\mathrm{B}_{\mathrm{d}} \rightarrow$ $\phi K_{S}$ decay，which are difficult to be explained in SM， but can be explained simultaneously in the 2HDM III． Moreover，if the recent experimental measurements on the polarization anomaly and $C P$ asymmetry are credible，these limits on the coupling parameters that we give out will really be interesting in searching for the signs of new physics．
