# Recent results of two－boson－exchange effects in the parity－violating elastic electron－proton scattering＊ 

ZHOU Hai－Qing（周海清）${ }^{1)}$<br>（Department of Physics，Southeast University，Nanjing 211189，China）

#### Abstract

The results of two－boson－exchange effects in the parity－violating elastic electron－proton scattering are reported based on a simple hadronic model．The corrections are calculated including the nucleon and $\Delta(1232)$ intermediate states．And the numerical results are also compared with the recent results reported by other group and other methods．

Key words two－boson－exchange，parity－violation，elastic electron－proton scattering，strange quark form factor

## 1 Introduction

The study of strange quark form factors of proton has attracted much interest during the last decade． Experimentally，the parity－violating elastic electron－ proton scatter provides a good method to extract such quantities．Significant progresses have been made during the last ten years ${ }^{[1-4]}$ and the non－ zero strange quark form factors are indicated from the precise measurement of parity asymmetry $A_{\mathrm{PV}}=$ $\frac{\sigma^{\mathrm{R}}-\sigma^{\mathrm{L}}}{\sigma^{\mathrm{R}}+\sigma^{\mathrm{L}}}$ in polarized electron－proton scattering．Such precise measurements call for precise theoretical esti－ mate of the radiative corrections．On another hand， it has been showed that the two－photon－exchange ef－ fects play important role in the unpolarized elastic electron－proton scattering ${ }^{[5,6]}$ ．It is a natural ques－ tion to ask how about the two－boson－exchange effects in the parity－violating elastic electron－proton scatter－ ing will be．In this letter，we report such results based on a simple hadronic model．

For parity－violating elastic electron－proton scat－ tering，the asymmetry $A_{\mathrm{PV}}$ at the tree level is ex－ pressed as

$$
\begin{equation*}
A_{\mathrm{PV}}^{1 \gamma+\mathrm{Z}}=-\frac{G_{\mathrm{F}} Q^{2}}{4 \pi \alpha \sqrt{2}} \frac{A_{\mathrm{E}}+A_{\mathrm{M}}+A_{\mathrm{A}}}{\left[\varepsilon\left(G_{\mathrm{E}}^{\gamma, \mathrm{P}}\right)^{2}+\tau\left(G_{\mathrm{M}}^{\gamma, \mathrm{P}}\right)^{2}\right]} \tag{1}
\end{equation*}
$$

with

$$
\begin{aligned}
& A_{\mathrm{E}}=\varepsilon G_{\mathrm{E}}^{\mathrm{Z}, \mathrm{P}} G_{\mathrm{E}}^{\gamma, \mathrm{P}}, \quad A_{\mathrm{M}}=\tau G_{\mathrm{M}}^{\mathrm{Z}, \mathrm{P}} G_{\mathrm{M}}^{\gamma, \mathrm{P}} \\
& A_{\mathrm{A}}=-\left(1-4 \sin ^{2} \theta_{\mathrm{W}}\right) \sqrt{\tau(1+\tau)\left(1-\varepsilon^{2}\right)} G_{\mathrm{A}}^{\mathrm{Z}} G_{\mathrm{M}}^{\gamma, \mathrm{P}}
\end{aligned}
$$

and $\tau=Q^{2} /\left(4 M^{2}\right), \varepsilon \equiv\left[1+2(1+\tau) \tan ^{2} \theta_{\text {Lab }} / 2\right]^{-1}$ ， where $Q^{2}=-q^{2}$ is the momentum transfer and $\theta_{\text {Lab }}$ is the laboratory scattering angle．The form factors are defined by the matrix elements of currents

$$
\begin{aligned}
\left\langle p^{\prime}\right| J_{\mu}^{\mathrm{Z}}|p\rangle & =\bar{u}\left(p^{\prime}\right)\left[F_{1}^{\mathrm{Z}, \mathrm{P}} \gamma_{\mu}+F_{2}^{\mathrm{Z}, \mathrm{p}} \frac{\mathrm{i} \sigma_{\mu \nu}}{2 M} q^{\nu}+G_{\mathrm{A}}^{\mathrm{Z}} \gamma_{\mu} \gamma_{5}\right] u(p), \\
\left\langle p^{\prime}\right| J_{\mu}^{\gamma}|p\rangle & =\bar{u}\left(p^{\prime}\right)\left[F_{1}^{\gamma, \mathrm{P}} \gamma_{\mu}+F_{2}^{\gamma, \mathrm{p}} \frac{\mathrm{i} \sigma_{\mu \nu}}{2 M} q^{\nu}\right] u(p)
\end{aligned}
$$

with

$$
G_{\mathrm{E}}^{\gamma(\mathrm{Z}), \mathrm{P}}=F_{1}^{\gamma(\mathrm{Z}), \mathrm{P}}-\tau F_{2}^{\gamma(\mathrm{Z}), \mathrm{P}}, G_{\mathrm{M}}^{\gamma(\mathrm{Z}), \mathrm{P}}=F_{1}^{\gamma(\mathrm{Z}), \mathrm{P}}+F_{2}^{\gamma(\mathrm{Z}), \mathrm{P}} .
$$

Using the contents of currents at quark level and assuming the charge symmetry

$$
\begin{align*}
& J_{\mu}^{\mathrm{em}}=\sum_{\mathrm{f}=\mathrm{u}, \mathrm{~d}, \mathrm{~s}} Q_{\mathrm{f}} \bar{q}_{\mathrm{f}} \gamma_{\mu} q_{\mathrm{f}}, \quad J_{\mu}^{\mathrm{Z}}=\sum_{\mathrm{f}} \bar{q}_{\mathrm{f}}\left(g_{\mathrm{V}}^{\mathrm{f}}+g_{\mathrm{A}}^{\mathrm{f}} \gamma_{5}\right) q_{\mathrm{f}}, \\
& G_{\mathrm{E}, \mathrm{M}}^{\mathrm{u}, \mathrm{~d}, \mathrm{~s} / \mathrm{p}}=G_{\mathrm{E}, \mathrm{M}}^{\mathrm{d}, \mathrm{~s} / \mathrm{n}} \tag{2}
\end{align*}
$$

the $A_{\mathrm{PV}}$ can be re－expressed as

$$
\begin{equation*}
A_{\mathrm{PV}}^{1 \gamma+\mathrm{Z}}=A_{1}+A_{2}+A_{3} \tag{3}
\end{equation*}
$$

[^0]Fig. 2. Two-boson-exchange corrections with N and $\Delta$ intermediate states to parity-violating asymmetry as functions of $\varepsilon$ from 0.1 to 0.9 at $Q^{2}=0.1,1.0,3.0$, and $5.0 \mathrm{GeV}^{2}$.

To extract the strange quark form factor from the experimental data, the correction at the zero momentum approximation should be subtracted to avoid the double counting. We do this $\mathrm{as}^{[8,9]}$ and define the correction $\delta_{\mathrm{G}}$

$$
\begin{equation*}
\bar{G}_{\mathrm{E}}^{\mathrm{s}}+\beta \bar{G}_{\mathrm{M}}^{\mathrm{s}}=\left(G_{\mathrm{E}}^{\mathrm{s}}+\beta G_{\mathrm{M}}^{\mathrm{s}}\right)\left(1+\delta_{\mathrm{G}}\right), \tag{5}
\end{equation*}
$$

where $\bar{G}_{\mathrm{E}}^{\mathrm{s}}+\beta \bar{G}_{\mathrm{M}}^{\mathrm{s}}$ are the form factors extracted from the experimental $A_{\mathrm{PV}}$ after considering two-boson exchange effects.

The results for such defined $\delta_{\mathrm{G}}$ are showed in Table 1 where the large corrections indicate the importance of two-boson-exchange effects.

Table 1. The corrections $\delta_{\mathrm{G}}$ to $G_{\mathrm{E}}^{\mathrm{s}}+\beta G_{\mathrm{M}}^{\mathrm{s}}$ for HAPPEX, $A 4$, and $G 0$ experiments. (I, II), (III, IV), and (V, VI) refer to the HAPPEX, $A 4$, and $G 0$ data, respectively.

|  | I | II | III | IV | V | VI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $Q^{2} / \mathrm{GeV}^{2}$ | 0.477 | 0.109 | 0.23 | 0.108 | 0.232 | 0.410 |
| $\epsilon$ | 0.974 | 0.994 | 0.83 | 0.83 | 0.986 | 0.974 |
| $\delta_{\mathrm{N}}(\%)$ | 0.25 | 0.34 | 0.86 | 1.30 | 0.288 | 0.275 |
| $\delta_{\Delta}(\%)$ | -0.59 | -1.53 | 0.21 | 0.66 | -0.90 | -0.60 |
| $\delta(\%)$ | -0.34 | -1.19 | 1.07 | 1.96 | -0.61 | -0.30 |
| $\delta_{0}(\%)$ | 1.03 | 2.62 | 1.51 | 3.13 | 1.82 | 1.417 |
| $\delta_{\mathrm{G}}(\%)$ | -25.52 | -75.23 | -2.76 | -2.27 | 13.12 | 20.62 |

Fig. 3. TPE and $\gamma \mathrm{Z}$-exchange corrections with N and $\Delta$ as intermediate states to parityviolating asymmetry as functions of $\varepsilon$. The above is for N case and the below is for $\Delta$ case. Dotted line denotes corrections coming from the interference between $1 \gamma$-exchange and $2 \gamma$-exchange, dashed lines denote corrections coming from the interference between 1Zexchange and $2 \gamma$-exchange and solid lines denote the corrections coming from the interference between $1 \gamma$-exchange and $\gamma \mathrm{Z}$-exchange.

The same effects are calculate by ${ }^{[11]}$ recently and similar properties are found. Moreover, the GDPs method ${ }^{[12]}$ is also used to discuss the two-bosonexchange effects, and the authors got different property for the $\gamma \mathrm{Z}$ contribution and argued such difference may come from the large momentum region. These suggest the two-boson-exchange effects in ep scattering call for further study. And how to to combine the GDPs methods and hadronic model is still an open issue.
